Abstract—Abstract is very abstract. Abstract is very abstract.

Index Terms—graph analysis, sparse linear algebra, Graph-BLAS API, GPGPU, parallel programming, functional programming, .NET, OpenCL

### I. INTRODUCTION

One of the promising ways to high-performance graph analysis is based on the utilization of linear algebra: operations over vectors and matrices can be efficiently implemented on modern parallel hardware, and once we reduce the given graph analysis problem to the composition of such operations, we get a high-performance solution for our problem. A wellknown example of such reduction is a reduction of all-pairs shortest path (APSP) problem to matrix multiplication over appropriate semiring. GraphBLAS API standard [?] provides formalization and generalization of this observation and make it useful in practice. GraphBLAS API introduces appropriate algebraic structures (monoid, semiring), objects (scalar, vector, matrix), and operations over them to provides building blocks to create graph analysis algorithms. It was shown, that sparse linear algebra over specific semirings is useful not only for graph analysis, but also in other areas, such as computational biology [?] and machine learning [?].

There are a number of GraphBLAS API implementations, such as SuiteSarse:GraphBLAS [?] and CombBLAS [?], but all of them do not utilize the power of GPGPU, except GraphBLAST [?], while GPGPU utilization for linear algebra

is a common practice today. GPGPU development is difficult itself because it introduces heterogeneous computational device, special programming model, and specific optimizations. Implementation of GraphBLAS API even more challenging, because it means the processing of irregular data, and the creation of generic (polymorphic) functions to declare and use user-defined semirings which is hard to express in low-level programming languages like CUDA C or OpenCL C which are usually used for GPGPU programming. Moreover, it is necessary to use high-level optimizations, like kernel fusion or elimination of unnecessary computations to improve the performance of end-user solutions based on the provided API implementation. But such high-level optimizations are too hard to automate for C-like languages.

Functional programming can help to solves these problems. First of all, native support functions as parameters simplify semirings descriptions and implementation of functions parametrized with semirings. Moreover, a powerful type system allows one to describe abstract (generic) functions which simplifies the development and usage of abstract linear algebra operations. Even more, such native features of functional programming languages, like discriminated unions (union types) and strong static typing allows one to create more robust code. For example, discriminated unions allows one naturally express Min-Plus semiring, where we should equip  $\mathbb{R}$  with special element  $\infty$  (infinity, namely identity element for  $\oplus$ ), so we cannot use predefined types like float or double. Another area where functional programming can be useful is automatic code optimization. A big number of nontrivial optimizations for functional languages for GPGPU were developed, such as specialization, deforestation, and kernels fusion, one of the actively discussed optimizations in GraphBLAS community [?]. These techniques make programs in high-level programming languages competitive in terms of performance with solutions written in CUDA or OpenCL C. For more details one can look at such languages and

Identify applicable funding agency here. If none, delete this.

frameworks as Futhark<sup>1</sup> [?], Accelerate<sup>2</sup> [?], AnyDSL<sup>3</sup> [?].

In this work we discuss a way to implement Graph-BLAS API which combines high-performance computations on GPGPU and the power of high-level programming languages in both application development and possible code optimizations. Our solution is based on metaprogramming techniques: we propose to generate code for GPGPU from a high-level programming language. Namely, we plan to generate OpenCL C from a subset of F# programming language. To translate F# to OpenCL C we use a Brahma.FSharp<sup>4</sup> which is based on F# quotations metaprogramming techniques<sup>5</sup>. Usage of F# simplifies both implementation of GraphBLAS API, making features of functional programming available, and its utilization in application development with high-level programming language on .NET platform. Moreover, as far as F# is a functional-first programming language, it should make it possible to use advanced optimization techniques and power of type system. Choice of OpenCL C as a target language is motivated by its portability: it is possible to run OpenCL C code on multi-thread CPU, on different GPGPUs (not only Nvidia), and even on FPGA [?], [?]. The utilization of FPGAs may open a way to hardware acceleration of sparse linear algebra and, as a result, of many solutions in different areas such as graph analysis, computational biology, machine learning.

This work in progress, so only tiny not optimized prototype is implemented, but our preliminary evaluation shows that !!!

## II. DESIGN PRINCIPLES

Basic principles of proposed design described in this section. Here we will use .NET-like style for generic types:  $\texttt{Type}_1\langle \texttt{Type}_2\rangle$  means that the type  $\texttt{Type}_1$  is generic and  $\texttt{Type}_2$  is a type parameter.

# A. Types of graphs, matrices, and operations

Suppose one have an edge-labelled graph G where labels have type  $\mathtt{T}_{\mathtt{lbl}}$ . Suppose also one declare a generic type  $\mathtt{Matrix}\langle\mathtt{T}\rangle$  to use this type for graph representation where type parameter  $\mathtt{T}$  is a type of matrix cell. It is obvious that type of cell of adjacency matrix of graph G should a special type which has only two values: some value of type  $\mathtt{T}_{\mathtt{lbl}}$  or special value Nothing. This idea can be naturally expressed using discriminated unions (or sum types) which actively used not only in functional languages such as F#, OCalm, or Haskell, but also in TypeScript etc. Moreover, the described case is widely used and there is a standard type in almost all languages

which supports discriminated unions:  $Option\langle T \rangle$  in F# or OCaml, or Maybe $\langle T \rangle$  in Haskell. In F# this type defined as presented in listing  $\ref{eq:thicker}$ ?

```
type Option<T> =
| None
| Some of T
```

Listing 1: Option type definition

Thus, to represent the graph G as a matrix one should use an instance of  $\mathtt{Matrix}\langle \mathtt{Option}\langle \mathtt{T}_{\mathtt{lbl}}\rangle\rangle$  of generic type  $\mathtt{Matrix}\langle \mathtt{T}\rangle$ . This way we can explicitly separate non-zero and zero cells in terms of sparse matrix: non-zero cells are cells with value  $\mathtt{Some}(\mathtt{x})$  for which  $\mathtt{x}$  should be stored, and zero cells are cells with value  $\mathtt{None}$ .

In these settings, natural type for binary operation is

$$\operatorname{Option}\langle T_1 \rangle \to \operatorname{Option}\langle T_2 \rangle \to \operatorname{Option}\langle T_3 \rangle.$$

But this type is not restrictive enough: it allows one to define operation which returns some non-zero (Some(x)) value for two zeroes (None-s), while we expect that

for any operation op.

To solve this problem one can introduce additional constraints, but such constraints can not be expressed in F#. An alternative solution is to introduce a type  $AtleastOne\langle T_1, T_2\rangle$  as presented in listing ??. This type is less flexible (for example it disallows one to apply operation partially) but is explicitly shows that we expect that at least one argument of operation should be non-zero.

Listing 2: AtLeastOne type definition

Finally in this settings operations should have the following type:

AtLeastOne
$$\langle T_1, T_2 \rangle \to \text{Option} \langle T_3 \rangle$$
.

This type disallows one to build non-zero value from two zeroes, and explicitly shows whether result should be stored or not. Thus, proposed typing scheme solves problem of explicit and implicit zeroes. Moreover it allows to generalize element-wise operations. For example, binary operations for element-wise addition, element-wise multiplication, and even for masking can be specified as presented in listings ??, ??, ?? respectively.

#### III. IMPLEMENTATION DETAILS

To evaluate ideas described above we start a development of library named GraphBLAS#<sup>6</sup>.

<sup>&</sup>lt;sup>1</sup>Futhark is a purely functional statically typed programming language for GPGPU. Project web page: https://futhark-lang.org/. Access date: 12.01.2021.

```
let op_int_mult args =
match args with
| Both (x, y) ->
    ler res = x * y
    if res = 0
    then None
    else Some res
| Left x -> None
| Right y -> None
```

Listing 4: An example of element-wise multiplication operation definition

We use a Brahma.FSharp library for running time translation of F# code to OpenCL C, and for translated kernels execution. Brahma.FSharp is based on code quotations, thus utilizes strong typing to provide more static code checks, and polymorphic first class functions for general highly abstract code creation. Additionally, Brahma.FSharp provides special workflow builder to simplify heterogeneous programming and automate resource management.

Abstraction layers which hides details of matrix representation and operations implementation. Currently we are working on COO and CSR formats and respective operations.

## IV. EVALUATION

While our implementation of GraphBLAS API is on very early stage, we cannot evaluate it on well-known linear algebra based algorithms. But in order to !!! Elementwise addition.

We perform our experiments on the PC with Ubuntu 18.04 installed and with the following hardware configuration: !!! CPU, !!! RAM, !!!GPGPU with !!!!.

our solution on CPU and GPGPU. For comparison we choose the following libraries.

- SuiteSparse as a ...
- Math.NET Numerics<sup>7</sup>
- GraphBLAST

#### V. CONCLUSION

We present a work in progress that demonstrates a way to utilize both a power of high-level languages and performance of GPGPUs to implement GraphBLAS API. Our preliminary evaluation shows that !!!

In the future, first of all, we should extend our library up to full GraphBLAS API implementation. Moreover, it may be

<sup>&</sup>lt;sup>7</sup>Library which provides numerical computations primitives for .NET: https://numerics.mathdotnet.com/. Access date: 12.01.2021.

<sup>&</sup>lt;sup>8</sup>!!!

<sup>&</sup>lt;sup>9</sup>BenchmarkDotNet allows one to automate benchmarking process for .NET platform. Project web page: https://benchmarkdotnet.org/. Access date: 12.01.2021.

useful for community to implement an analog of LAGraph<sup>10</sup> algorithms collection for .NET on the top of our GraphBLAS API implementation.

The next step is evaluation of the solution on real-world cases and comparison with other implementations of Graph-PLAS API on different devices and different algorithms. Additionally, it may be interesting to compare our solution with graph analysis libraries and with linear algebra libraries for .NET platform.

Another direction of future work is Brahma.FSharp improvements. First of all, it is necessary to support discriminated unions to make it possible to express custom semirings such as Min-Plus, as presented in listing ??.

Also, it is necessary to add high-level abstractions for both asynchronous programming and for multi-GPU programming. Such mechanisms can be naturally expressed in F# with native primitives for asynchronous programming, and by using high-level abstractions for multiple GPUs management.

Finally, we plan to implement high-level optimizations, like fusion and specialization in Brahma.FSharp.
